

Program features (Jackson's writeup):

- The program allows for the user to scrape data from a website, with the website loading automatically once the user inputs a link to the website. The user can then interact with the program to choose elements to scrape, what to do with scraped data and even advanced settings to manage scraping more personally by being more involved in the process.
- The user can take scraped data and send it to label studio to allow for active labeling of the scraped data, such as providing context to a word that would allow for the NLP to properly consider that word's tone in its training.
- The program also contains a database which will store the information it gains and allow for that data to be accessed and modified as is needed.
- The program also contains an NLP (natural language processing) tool which will analyze tone in the scraped data, analyzing all of the data that is provided to it to analyze and provide data on the general tone and extent of usage of words (specifically for this project, words about drug users, drug use and drugs themselves in order to provide information on the general diction in use when discussing drug addiction).
- The program also has internal features meant to allow for customization of basic aspects such as appearance to match the user's preferences.
